What’s new and Why?

Multiple Valve Disease

Christophe Tribouilloy
Amiens, France
I have no financial relationships to disclose related to this presentation.
8.5 Medical therapy
Diuretics reduce congestion. Specific therapy of the underlying disease is warranted.

9. Tricuspid stenosis
Tricuspid stenosis (TS), which is mostly of rheumatic origin, is rarely observed in developed countries although it is still seen in developing countries.\textsuperscript{3,2} Detection requires careful evaluation, as it is almost always associated with left-sided valve lesions that dominate the presentation.

9.1 Evaluation
Clinical signs are often masked by those of the associated valvular lesions, especially MS.\textsuperscript{12,190} Echocardiography provides the most useful information. TS is often overlooked and requires careful evaluation. The pressure half-time method is less valid for the assessment of the severity of TS than of MS and the continuity equation is rarely applicable because of the frequency with which associated regurgitation is present. Planimetry of the valve area is usually impossible unless 3DE is used. No generally accepted grading of TS severity exists. A mean gradient ≥5 mmHg at normal heart rate is considered indicative of clinically significant TS.\textsuperscript{13} Echocardiography should also examine the presence of commissural fusion, the anatomy of the valve and its subvalvular apparatus, which are the most important determinants of repairability and the degree of concomitant TR.

9.2 Surgery
The lack of pliable leaflet tissue is the main limitation for valve repair. Even though this is still a matter of debate, biological prostheses for valve replacement are usually preferred over mechanical ones because of the higher risk of thrombosis carried by the latter and the satisfactory long-term durability of the former in the tricuspid position.\textsuperscript{188–191}

9.3 Percutaneous intervention
Percutaneous balloon tricuspid dilatation has been performed in a limited number of cases, either alone or alongside PMI, but this frequently induces significant regurgitation. There is a lack of data on evaluation of long-term results.\textsuperscript{192}

9.4 Indications for intervention
Intervention on the tricuspid valve is usually carried out at the time of intervention on the other valves in patients who are symptomatic despite medical therapy. Conservative surgery or valve replacement—according to anatomy and surgical expertise in valve repair—is preferred to balloon commissurotomy, which can only be considered as a first approach in the rare cases of isolated TS (Table 16).

9.5 Medical therapy
Diuretics are useful in the presence of HF—but of limited efficacy.

10. Combined and multiple valve diseases
Significant stenosis and regurgitation can be found on the same valve. Disease of multiple valves may be encountered in several conditions, but particularly in rheumatic heart disease and, less frequently, in degenerative valve disease. There is a lack of data on mixed and multiple valve diseases. This does not allow for evidence-based recommendations.\textsuperscript{190}

The general principles for the management of mixed or multiple valve disease are as follows:

- When either stenosis or regurgitation is predominant, management follows the recommendations concerning the predominant VHD. When the severity of both stenosis and regurgitation is balanced, indications for interventions should be based upon symptoms and objective consequences, rather than the indices of severity of stenosis or regurgitation.
- Besides the separate assessment of each valve lesion, it is necessary to take into account the interaction between the different valve lesions. As an illustration, associated MR may lead to underestimation of the severity of AS, since decreased stroke volume due to MR lowers the flow across the aortic valve and, hence, the aortic gradients. This underlines the need to combine different measurements, including assessment of valve areas, if possible using methods that are less dependent on loading conditions, such as planimetry.
- Indications for intervention are based on global assessment of the consequences of the different valve lesions, i.e. symptoms or presence of LV dilatation or dysfunction. Intervention can be considered for non-severe multiple lesions associated with symptoms or leading to LV impairment.
- The decision to intervene on multiple valves should take into account the extra surgical risk of combined procedures.
- The choice of surgical technique should take into account the presence of the other VHD. Although repair remains the ideal option, the desire to repair one valve may be decreased if prosthetic valve replacement is needed on another.

The management of specific associations of VHD is detailed in the individual sections.

11. Prosthetic valves
Patients who have undergone previous valve surgery accounted for 28% of all patients with VHD in the Euro Heart Survey.\textsuperscript{1} Optimal choice of valve substitute—as well as subsequent management of patients with prosthetic valves—is essential to reduce prosthetic-related complications.

11.1 Choice of prosthetic valve
There is no perfect valve substitute. All involve some compromise and all introduce new disease processes, whether they are mechanical (single tilting disc and bileaflet valves) or biological. The latter include homografts, pulmonary autografts and porcine, pericardial bovine or equine bioprostheses. Xenograft valves can be further subdivided into stented and stentless. Stentless valves may have better haemodynamics but no improvement in long-term

ESC 2012 valve Guidelines - Include 46 pages,
- 1 short paragraph on multiple VHD
There is a lack of data on mixed and multiple VHD. This does not allow for evidence-based recommendations.
AHA/ACC 2008 Guidelines on the Management of VHD (page e64)

- « Other than recommending evaluation with physical examination, echocardiography, and cardiac catheterization …, the committee has developed no specific recommendations in multiple VHD . »
Multiple VHD are frequent

1010 necropsies in patients with VHD (age ≥ 15 years) 30% of multiple VHD

Causes of multiple VHD

- Rheumatic VHD
- Degenerative calcific VHD (elderly)
- Infective endocarditis
- Radiation therapy
- Drug-induced VHD (anorectic agents, ergot-derived agonist)
- Carcinoid VHD
- Congenital VHD
Evaluation of Multiple VHD

• Combined effects of each valvular lesion
• Echocardiographic evaluation (pitfalls)
  – Echo parameters validated in single-VHD
  – Haemodynamic interactions between valve lesions
  – combined different echo parameters
  – Measurements less dependent on loading conditions (direct planimetry, ERO, vena contracta…)
• Catheterization, CT, MRI
Assessment of Severity of Multiple VHD

Moderate VHD + Moderate VHD may lead to severe VHD
Extra Surgical Risk of combined surgery
Operative Mortality

Clinical case

- Man, 79 yo,
  Dyspnea NYHA class II-III despite medical treatment (furosemide 40mg)
  Normal coronary artery
  Moderate renal failure
  Logistic Euroscore  6 %

- Severe AS
  Severe organic MR (P3 prolapse)
  Mild TR
  LV dilatation,  EF=75%, mild PAH (SPAP 50mmHg)

- Decision making: **AVR + MV repair**
Severe Mitral Regurgitation
Pitfalls for Evaluation of severity of AS

• Severe MR despite preserved EF may:
  – decrease SV and gradient across Ao valve
  – conceale a severe AS behing a low gradient (low flow- low gradient AS)
• Severe MR may mask a significant LVD behind a normal EF
• AF, which frequently complicates MR, may:
  – decrease functional tolerance
  – decrease EF, forward SV, and Ao gradient
Severe MR + Severe LF-LG AS

BSA 1.82 cm²
LVOT diameter 1.9 cm; LVOT VTI 20 cm
SV 56.6 ml / indexed SV 31 ml/m²

Ao Peak Velocity 3.5 m/s
Mean gradient 33 mmHg
AVA 0.81 cm²; 0.45 cm²/m²
Clinical case

- Man, 81 yo,
- History of hypertension
- Dyspnea NYHA class IIb
- Severe calcified AS
- Secondary MR
- Mild MV calcification
- Normal EF
Severe calcified AS

BSA 1 85.cm²
LVOT diameter 2cm;
LVOT VTI 30 cm
SV 94 ml
indexed SV 51ml/m²

Ao Peak Velocity 4.45 m/s
Mean gradient 44 mmHg
AVA 0.82cm² ; 0.44 cm²/m²
Max area 15 cm²

Vena contracta 5mm
R = 0.80 cm

Aliasing Vel. = 30 cm/s

Mitral Peak Vel. 5.70 m/s,

Mitral VTI = 217 cm

ERO = 0.22 cm²

RV = 46 ml
Clinical case

- Man, 81 yo, history of hypertension (enalapril 20mg)
- Dyspnea NYHA class IIb
- Normal coronary artery
- Logistic Euroscore 7%

- Severe calcified AS,
- Secondary MR (ERO 0.22cm²)
- Mild to moderate mitral annular calcification
- no TR, tricuspid annular diameter 36mm
- LVH, EF=62%,

Decision making: Isolated AV replacement
(Trifecta Aortic Bioprosthesis)
decision making: isolated AV replacement (Trifecta Aortic Bioprosthesis)

As expected, the functional MR decreased significantly post operatively towards a mild degree
Severe Aortic Stenosis
Pitfalls for Evaluation of MR

• AS may worsen MR through several mechanisms
  – AS increases LV to LA systolic pressure gradient leading to increase, for any given ERO, the RV and the regurgitant jet area of MR
  – AS leads to chronic pressure overload and LV remodeling which may promote MV deformation and functional MR

• After isolated AVR, severity of functional MR generally decreases greatly and early:
  – systolic LV pressure and mitral gradient drop
  – acute reverse LV remodeling after AVR may lead to improvement in functional MR
Quantitative changes in MR after AV replacement

 Intervention in Multiple VHD

General principles from ESC VHD Guidelines

• Indications for intervention based on
  – global assessment of the consequences of different valve lesions on symptoms and on LV dysfunction, LA dilatation....
  – operative risk
  – discuss surgery for combined non-severe multiple lesions leading to symptoms, LVD ...

• Choice of surgical technique:
  – Repair: the ideal option
  – Desire to repair may be decreased if prosthetic valve replacement is needed on another
Multiple valve diseases are frequent
Evaluation is challenging
  – Haemodynamic interactions between lesions
  – Global consequences on symptoms, LV ….
  – Tricuspid valve

Management strategy: Heart Team
  – each case must be considered individually
  – Take into account increased operative risk of multiple valve surgery versus risk of leaving a valve unoperated
The « Heart Team »

Multiple VHD

each case of multiple VHD must be considered individually

Treatment of Valve disease

- CARDIOLOGISTS
- SURGEONS
- Anesthesiologists
- Other specialists: Geriatricians ...
- Imaging specialists (Echo, CT, MRI)
